Identifying soldierflies and allies: robberflies in genus *Dioctria*

Compiled by Martin C. Harvey for the Soldierflies and Allies Recording Scheme

Version 1 at 7 September 2020

These guides are only possible thanks to the generosity of the brilliant photographers who have allowed their images to be used. Special mention must be given to Malcolm Storey and Steven Falk, whose photo collections form the backbone for most of the species guides:

Malcolm Storey's <u>Biolmages website</u> – Steven Falk's <u>photo collections on Flickr</u>

Other photographers included in this guide are Dick Belgers, Ian Andrews, Jeremy Early, Kate Nightingale, Martin Harvey, Rob Petley-Jones, Sue Taylor and Tim Worfolk.

Males and females are similar for most of the species in this genus, and there is one page for each species. Distribution maps are taken from the recording scheme's provisional atlas (Harvey 2017).

As far as possible, these guides show features that can be seen on live insects in the field, or are likely to be visible in photographs. For comprehensive identification keys and species accounts see <u>British</u> <u>soldierflies and their allies</u>, by Alan Stubbs and Martin Drake. See also the recording scheme's <u>additional notes</u> to accompany the Stubbs and Drake keys.

For lots more information on soldierflies and allies go to the recording scheme <u>website</u>, <u>Twitter</u> page or <u>Facebook</u> group.

For lots more information and events, and to support the study and conservation of flies, please consider joining Dipterists Forum.

Records wanted!

Once you have identified your fly, please let the recording scheme have the details!
Add to <u>iRecord</u> or send to the <u>recording scheme</u> so that we can share the records for conservation and research.

The Soldierflies and Allies Recording Scheme is part of Dipterists Forum

The Soldierflies and Allies Recording Scheme is supported by the UKCEH Biological Records Centre

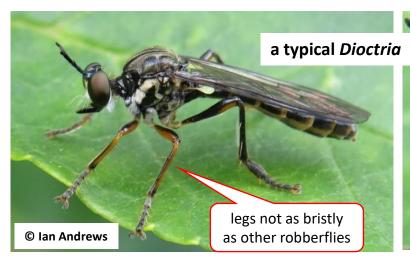

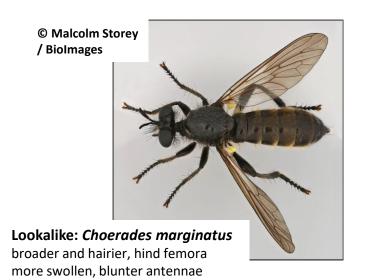

Recognising the genus: Dioctria

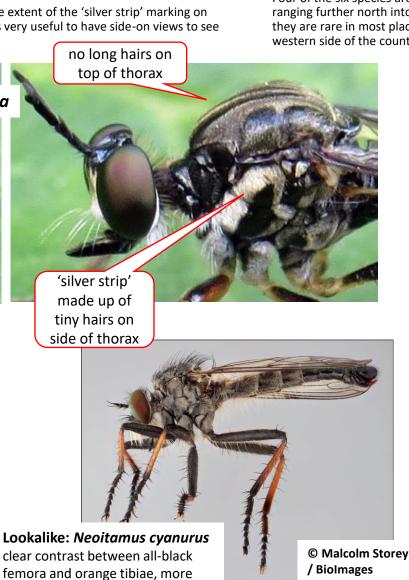

There are six UK species in genus *Dioctria*, within the robberfly family, Asilidae. They have the typical robberfly shape, with a long and narrow abdomen, narrow wings and head with large eyes and a small pointed proboscis. *Dioctria* are less hairy and bristly than many other robberflies, but there is room for confusion with some other genera such as *Choerades* and *Neoitamus*. For robberflies they are medium-sized, 8–15mm long.

Useful features to tell the species apart include the leg colours and the extent of the 'silver strip' marking on the side of the thorax. This means that when photographing them it is very useful to have side-on views to see the logs and side of the thorax.

the legs and side of the thorax.

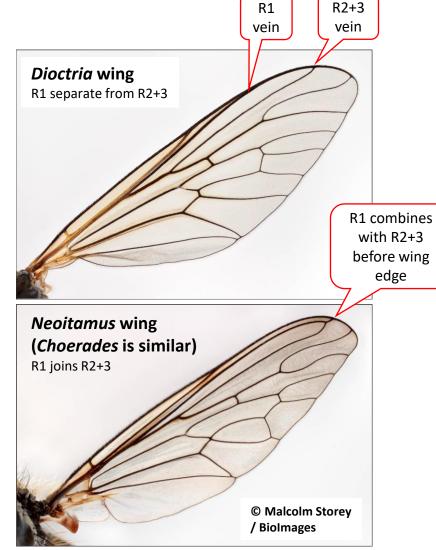

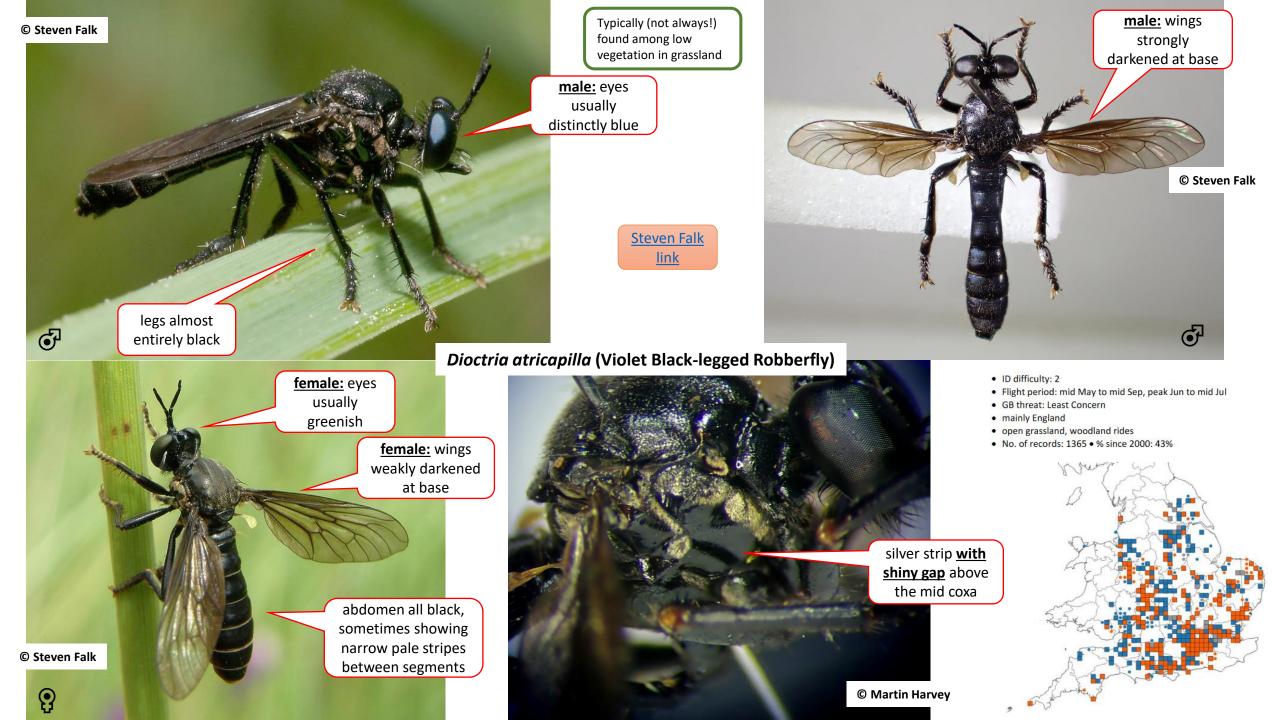

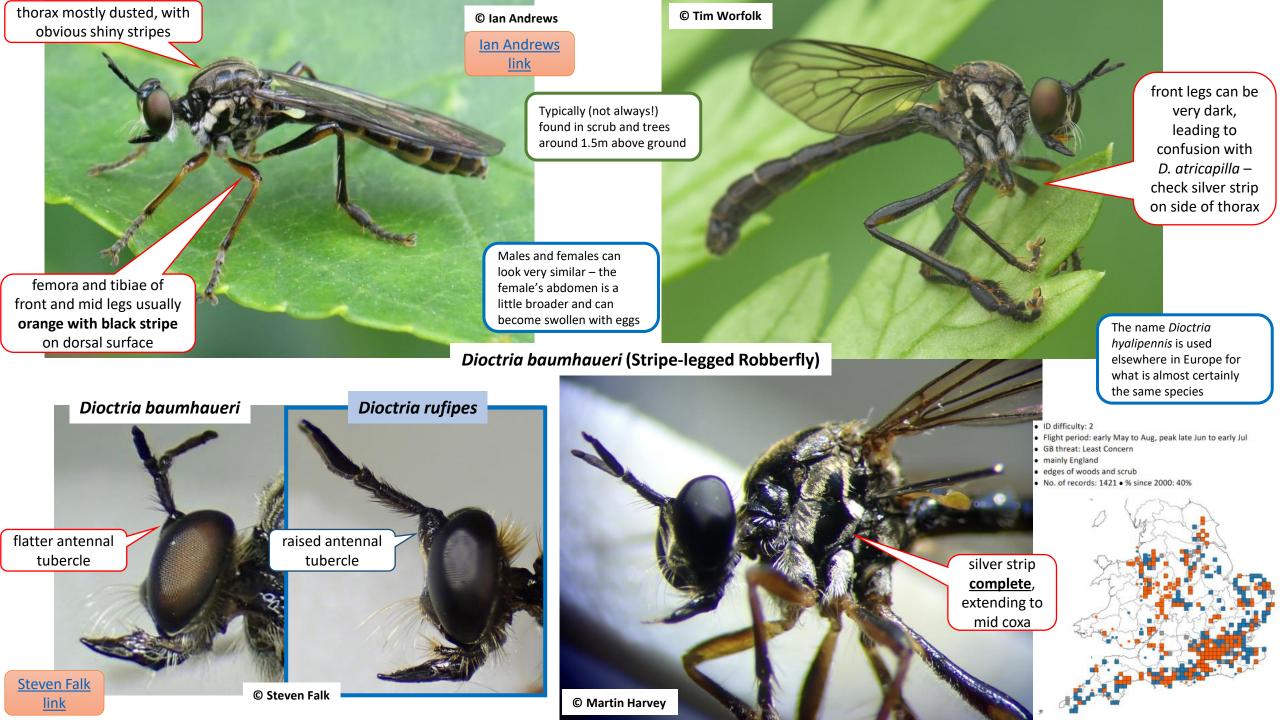

bristly, antennae more pointed

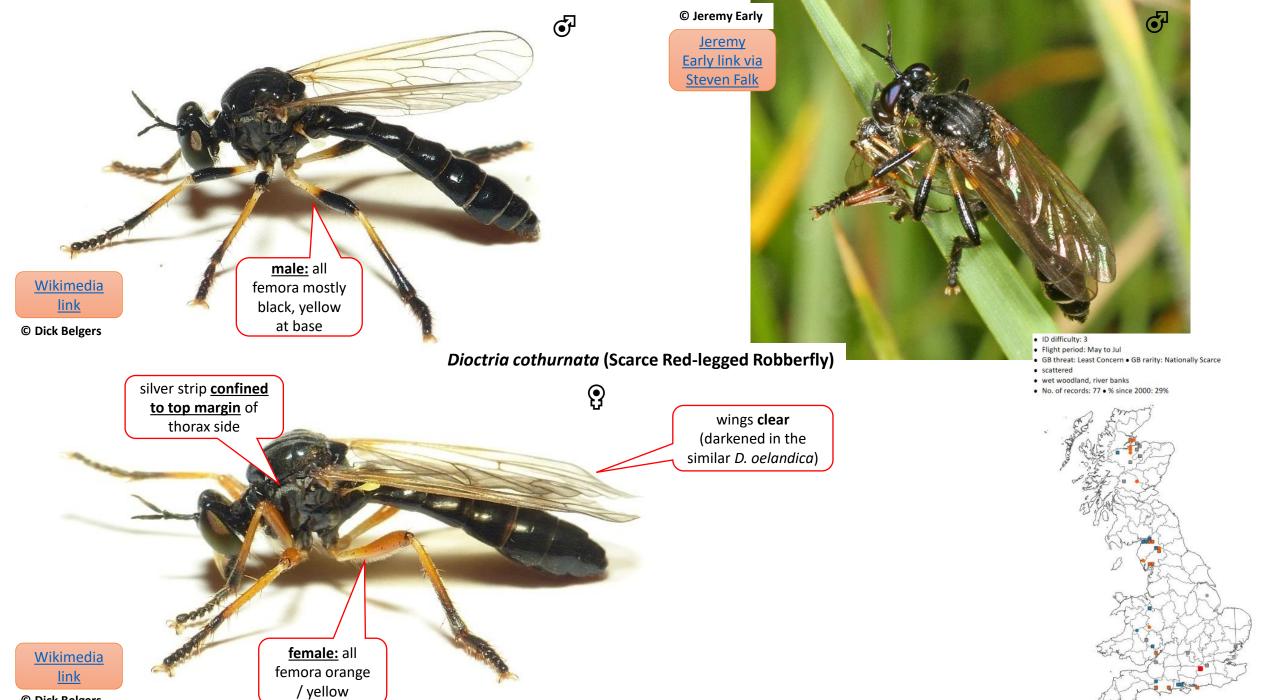

Most *Dioctria* are species of woodland and scrub edges, plus *D. atricapilla* which is more often found in open grassland. The adults are predators of a wide range of other insects, and their larvae are also thought to be predators, developing in the soil, although little seems to be known about their exact preferences.

Four of the six species are fairly common and widespread in the southern half of the UK, with *D. rufipes* ranging further north into Scotland. *D. cothurnatus* and *D. oelandica* have rather puzzling distributions – they are rare in most places but found at widely scattered locations across the UK, most often on the western side of the country.

Typically (not always!) found in tall vegetation and scrub up to 1m above ground

> femora and tibiae of front two pairs of legs almost entirely clear orange

Males and females can look very similar – the female's abdomen is a little broader and can become swollen with eggs
